Received 30 October 2021; accepted 3 December 2021

We study lepton flavor violation (LFV) within the Littlest Higgs Model with T parity (LHT) realizing an inverse seesaw (ISS) mechanism of type I. In this scenario there appear new \( \mathcal{O} \) (TeV) Majorana neutrinos, driving LFV. We analyze the heavy Majorana neutrinos effects on LFV processes; \( \ell \to \ell' \gamma \), \( Z \to \ell \ell' \), \( L \to 3 \ell \) decays and \( \mu \to e \gamma \) conversion in nuclei, but we emphasize Type III decay channel of \( L \to 3 \ell \) which are known as “wrong-sign”; \( \ell \to e \ell'' \ell''' \) satisfying \( \ell \neq \ell'' \neq \ell''' \), since these processes vanish in the traditional LHT. First, we obtain limits to \( |\theta_{\ell \ell'}|^{2}, |\theta_{\ell \ell''}|^{2}, \) and \( |\theta_{\mu e}|^{2} \) through \( \ell \to \ell' \gamma \). Using these limits for the product of the mixing angles, we can demonstrate that results for branching ratios of wrong-sign processes yield within one order of magnitude below present bounds. We do not expect large correlations between the two wrong-sign decay modes. Also, we see that the mean values of heavy Majorana neutrino masses for all LFV processes are quasi-degenerate around 4 TeV [1].

Keywords: Discrete symmetries; beyond standard model; technicolor and composite models.

DOI: https://doi.org/10.31349/SuplRevMexFis.3.020704

1. Introduction

Despite SM is a theory which describes all known elementary particles processes successfully, it has a severe problem due to the Higgs mass squared receives quadratically divergent radiative corrections coming from the interactions with SM fields. Over time several models have been proposed trying to solve this problem. Little Higgs models [2, 3] offer an explanation to the little hierarchy between the Higgs mass \( M_{h} \), assumed to be near the electroweak scale \( v = 246 \text{ GeV} \) and the new physics (NP) scale \( f \), whose value is expected to be \( \sim 1 \text{ TeV} \) [4–6]. In this set of models, the Higgs boson is originated as a pseudo-Nambu-Goldstone boson (pNGB) of a spontaneously broken global symmetry. Specifically, the Littlest Higgs model with T-parity (LHT) [2, 3, 7–11] is one of the most attractive such frameworks. LHT is based on the coset space \( SU(5)/SO(5) \), where \( SU(5) \) is the global symmetry broken by a vacuum expectation value (vev) at a scale of few TeV. The vev is represented by a \( 5 \times 5 \) symmetric tensor [12, 13]

\[
\Sigma_{0} = \begin{pmatrix}
0 & 0 & 1 & 0 & 0 \\
0 & 1 & 0 & 0 & 0 \\
I & 0 & 0 & 0 & 0
\end{pmatrix}. \tag{1}
\]

As \( SU(5) \) has 24 generators, after symmetry breaking, the 10 unbroken \( SO(5) \) generators satisfy

\[
T_{a} \Sigma_{0} + \Sigma_{0} T_{a}^{T} = 0, \tag{2}
\]

whereas the 14 broken generators obey

\[
X_{a} \Sigma_{0} - \Sigma_{0} X_{a}^{T} = 0. \tag{3}
\]

Goldstone bosons are fluctuations around this background in the broken directions \( \Pi \equiv \pi^{a} X^{a} \), and can be parameterized by the non-linear sigma model field

\[
\Sigma(x) = e^{i\Pi/f} \Sigma_{0} e^{i\Pi^{T}/f} = e^{i2\Pi/f} \Sigma_{0}, \tag{4}
\]

where \( f \) is the NP energy scale. Thus the matrix of NGB can be written as [12, 14]

\[
\Pi = \begin{pmatrix}
\chi + \frac{n}{2\sqrt{s}} & h_{1} & \phi \\
\frac{h_{1}}{\sqrt{2}} & \frac{h_{2}}{\sqrt{2}} & \phi^{T} \\
\phi^{T} & \chi^{T} + \frac{n}{2\sqrt{s}} & 0
\end{pmatrix}. \tag{5}
\]

The content of NGB is as follows: \( \phi \) is a complex \( SU(2)_{L} \) triplet; \( \chi \) and \( \eta \) are the Goldstone bosons which become the longitudinal modes of the T-odd gauge fields. They are written explicitly as

\[
\phi = \begin{pmatrix}
-\sqrt{2} i \Phi^{++} & -\sqrt{2} i \Phi^{+} \\
\Phi^{+} & -\frac{\Phi^{0} + \Phi^{\prime}}{\sqrt{2}}
\end{pmatrix}, \tag{6}
\]

\[
\chi = \begin{pmatrix}
-\omega^{0}/\sqrt{2} & -\omega^{+}/\sqrt{2} \\
-\omega^{-}/\sqrt{2} & \omega^{0}/\sqrt{2}
\end{pmatrix}. \tag{7}
\]

so, the fields \( \omega^{\pm}, \omega^{0} \) and \( \eta \) are eaten by the heavy gauge bosons \( W_{H}^{\pm}, Z_{H} \), and \( A_{H} \), respectively. \( h \) is the SM Higgs doublet

\[
h = \begin{pmatrix}
-\sqrt{2} i \nu^{+}/\sqrt{2} \\
\nu^{+} + \nu^{-}
\end{pmatrix}. \tag{8}
\]

The discrete T-parity symmetry is a \( Z_{2} \) one (similar to R-parity in SUSY), where SM particles are even under it (T-even), while the new particles at the TeV scale are odd (T-odd). T-parity forbids singly-produced heavy particles (odd under T) and tree level corrections to observables with only SM particles. As a result, direct and indirect constraints on the LHT are significantly relaxed [14, 15], and corrections to EWPO are generated at loop level. Thus, the LHT remains phenomenologically viable [12, 16–37].
LHT belongs the Product Group models, so the gauge group is taken to be \( G_1 \times G_2 = [SU(2) \times U(1)]^2 \), subgroup of the SU(5) global symmetry. A natural action of T-parity on the gauge fields is defined as
\[
G_1 \leftrightarrow G_2.
\]

In the gauge sector before EWSB, the SM (light) gauge bosons are \( W^\pm \) and \( B_L \), which are massless and T-even, while the massive heavy gauge bosons (T-odd) are \( W^\pm_H \) and \( B_H \). After high energy symmetry breaking, their masses are [15]
\[
M_{W^\pm_H} = g_W f, \quad M_{B_H} = \frac{g_f f}{\sqrt{6}},
\]
where \( e = g_W s_W = g' c_W \).

When EWSB is included, the masses of SM bosons are given by [12, 15]
\[
M_{W^\pm} = \frac{g_W v}{2} \left( 1 - \frac{v^2}{6 f^2} \right)^{1/2} \approx \frac{g_W v}{2} \left( 1 - \frac{v^2}{12 f^2} \right),
\]
\[
M_{Z_H} = \frac{g_W v}{2 \cos \theta_W} \left( 1 - \frac{v^2}{6 f^2} \right)^{1/2} = \frac{M_{W^\pm}^2}{\cos \theta_W},
\]
\[
M_{A_L} = 0.
\]

It is important to observe that \( \rho \) factor is conserved in LHT in contrast to SLH, since in the latter model \( \rho \) has corrections of the order of \( v^2/f^2 \).

In the heavy sector the masses are written as follows [12, 15]
\[
M_{W^\pm_H} = M_{Z_H} = f g_W \left( 1 - \frac{v^2}{4 f^2} \right)^{1/2} \approx f g_W \left( 1 - \frac{v^2}{8 f^2} \right),
\]
\[
M_{A_H} = \frac{g_f}{\sqrt{5}} \left( 1 - \frac{5v^2}{4 f^2} \right)^{1/2} \approx \frac{g'_f}{\sqrt{5}} \left( 1 - \frac{5v^2}{8 f^2} \right) .
\]

Including fermion sector is less straightforward than scalar one. For each SM lepton doublet, two doublets \( \psi_1 \) and \( \psi_2 \) are introduced by an incomplete representation \( \Psi_1, \Psi_2 \in SU(5) \) symmetry. The field content can be expressed as follows (\( \sigma^2 \) is the second Pauli matrix)
\[
\psi_1 = \begin{pmatrix} \psi_1 \\ 0 \\ 0 \\ 0 \\ 0 \end{pmatrix}, \quad \psi_2 = \begin{pmatrix} 0 \\ 0 \\ 0 \\ \psi_2 \\ \nu_2 \end{pmatrix},
\]
\[
\bar{\psi}_i = -i \sigma^2 \begin{pmatrix} \nu_{iL} \\ \ell_{iL} \end{pmatrix},
\]
with \( i = 1, 2 \), where \( \Psi_2 \) transforms with the fundamental \( SU(5) \) representation \( V \) and \( \Psi_2 \) with its complex conjugated. T-parity is defined to act on the left-handed (LH) leptons as
\[
\Psi_1 \leftrightarrow \Omega \Sigma_0 \Psi_2,
\]
with
\[
\Omega = \text{diag}(-1, -1, 1, -1, -1),
\]
\[
\Sigma_0 = \begin{pmatrix} 0 & 0 & 1_{2 \times 2} \\ 0 & 1 & 0 \\ 1_{2 \times 2} & 0 & 0 \end{pmatrix}.
\]

The T-even combination of \( \psi_1 \) and \( \psi_2 \) will be identified as the SM electroweak leptons
\[
\psi_{SM} = \frac{1}{\sqrt{2}} (\psi_1 - \psi_2),
\]
which receives mass after EWSB from Yukawa interactions, while T-odd combination, defined as follows
\[
\psi_{HL} = \frac{1}{\sqrt{2}} (\psi_1 + \psi_2),
\]
refers to a Dirac mass of order \( O(f) \). This heavy eigenstate gets its mass combining with an additional set of fermions in a T-odd SO(5) multiplet \( \psi_R \), which is right-handed
\[
\Psi_R = \begin{pmatrix} \psi_R^-$ \\ \chi_R \\ \psi_{HR} \end{pmatrix}, \quad T : \Psi_R \leftrightarrow \Omega \Psi_R.
\]

It is important that Yukawa Lagrangian be invariant under \( SU(5) \) and T-parity, thus with aid of \( \xi = \exp (i \Pi / f) \) field, it will be written
\[
\mathcal{L}_{Y_H} = \kappa_1 f (\bar{\Psi}_2 \xi + \bar{\Psi}_1 \Sigma_0 \xi^\dagger) \Psi_R = \sqrt{2} \kappa_1 f \bar{\psi}_{HL} \psi_{HR} + \cdots .
\]

We see that T-odd combination receives a Dirac mass \( M_\nu = \sqrt{2} \kappa_1 f \), whereas the T-even combination \( \psi_{SM} \) remains massless, as we expected. After EWSB, a small mass splitting between the T-odd leptons and neutrinos is induced at order of \( O(v^2/f^2) \), becoming
\[
m_{\nu_H} = \sqrt{2} \kappa_1 f \left( 1 - \frac{v^2}{8 f^2} \right), \quad m_{\ell_H} = \sqrt{2} \kappa_1 f.
\]

2. New contributions to LFV processes

As we know, the SM contributions to the LFV processes like \( \mu \to e \gamma \) and \( \mu \to e \epsilon \bar{e} \) are negligible since they are proportional to the neutrino masses. Nevertheless, we expect that LHT contributions have a sizeable effect in LFV due to the exchange of the new vector bosons and heavy fermions coming from the T-parity.

Two types of diagrams contribute to \( \mu \to e \nu \nu \), which are shown in Fig. 1.

![Figure 1. Generic penguin and box diagrams for \( \mu \to ee \bar{e} \).](image_url)
3. Extracting form factors from the $\ell \to \ell' \gamma$ amplitude

Most general structure of the $\ell \to \ell' \gamma$ effective vertex can be expressed in terms of six form factors

$$i\Gamma^\mu(p_1, p_2) = ie \left[ \gamma^\mu \left( F^V_L p_L + F^V_R p_R \right) + (i F^V_M + F^V_E \gamma_5)Q \sigma^{\mu\nu}Q \nu + (i F^V_S + F^V_P \gamma_5)Q^\mu \right],$$

with $Q = p_2 - p_1$ the vector boson momentum entering the vertex. Under the consideration that the photon is on-shell, only the dipole form factors $F^\gamma_M$ contribute.

In Fig. 2 we show the topologies of the diagrams that contribute to the $V - \ell - \ell'$ ($V = \gamma/Z$) effective vertex.

The form factor $F^\gamma_M$ is given by the contributions [35]

$$F^\gamma_M = \gamma_L^\mu |W_H + F^\gamma_M \gamma_H + F^\gamma_M \gamma_E \nu + F^\gamma_M \gamma_P |\nu + F^\gamma_M |\nu. \hspace{1cm} (22)$$

There are two additional contributions coming from the exclusive fermion content of LHT (they had not been considered until [35]). The contributions from partner leptons $\hat{e} = (\nu^c, \bar{e}^c)$ only involve topologies III, IV, IX and X (see Fig. 2), because they do not couple to one T-odd gauge boson and a SM charged lepton. We computed all form factors with aid of Package-X [41]. Then, neglecting $m_{\ell'} \ll m_{\ell}$, we obtain

$$\Gamma(\ell \to \ell' \gamma) = \frac{\alpha}{2} m^2_{\ell} (|F^\gamma_M|^2 + |F^\gamma_P|^2). \hspace{1cm} (23)$$

4. Extracting form factors from the $\mu \to eee$ amplitude

This process can be studied like a $\ell \to \ell' \ell' \ell'$ decay which involves photon and Z penguin diagrams as well as box contributions.

The effective vertex reads as follows

$$i\Gamma^\mu(p_1, p_2) = ie \left\{ [i F^M_H(Q^2) + F^M_E(Q^2)\gamma_5] \sigma^{\mu\nu}Q \nu + F^M_L(Q^2)\gamma^\mu p_\nu \right\}, \hspace{1cm} (24)$$

with $Q = (p_{\ell'} - p_\ell)_{\mu}$. In our case $\ell' = \mu$ and $\ell' = e$, therefore the corresponding right-handed vector form factor vanishes ($m_e \approx 0$). Due to the constraints of LHT only photon and Z penguin diagrams contribute, since $A_H$ and $Z_H$ do not couple to two SM fermions.

In the $\gamma$-penguin contribution the $F^\gamma_M$ and $F^\gamma_E$ form factors have the same expressions as Eq. (22). For an on-shell photon, terms proportional to $Q^2$ vanish. Hence, the $F^\gamma_L$ form factor receives the following contributions [35]

$$F^\gamma_L = F^\gamma_L |W_H + F^\gamma_L \gamma_H + F^\gamma_L \gamma_E \nu + F^\gamma_L \gamma_P |\nu + F^\gamma_L |\nu. \hspace{1cm} (25)$$

In the $Z$-penguin contributions the dipole form factors $F^Z_M$, which are chirality flipping and hence proportional to the muon mass, vanish when they are compared to $F^Z_P$. Thus, at leading order the $Z\ell\ell'$ vertex reduces to

$$i\Gamma^\nu(p_1, p_2) = ie F^Z_L(Q^2)\gamma^\nu p_L, \hspace{1cm} (26)$$

where we obtain [35]

$$F^Z_L = F^Z_L |W_H + F^Z_L \gamma_H + F^Z_L \gamma_E \nu + F^Z_L \gamma_P |\nu + F^Z_L |\nu. \hspace{1cm} (27)$$

The amplitude due to box diagrams is given by

$$\mathcal{M}^\ell(\ell' \to \ell' e e) = e^2 B_L(0)\bar{p}_1(\gamma^\mu \times P_L u(p_1)\bar{P}_3(\gamma^\mu P_L v(p_2). \hspace{1cm} (28)$$

Figure 3 shows the box diagrams contributing to $\mu \to eee$ decay. The whole $B_L(0)$ form factor receives the following contributions [35]
We expect the new interactions that appear from the heavy particles (T-odd) to contribute sizeably to LFV processes called “wrong sign”: $\ell \rightarrow \ell' \ell'' \ell'''$ with $\ell \neq \ell' = \ell'' \neq \ell'''$. We can see in Table I limits on LFV processes presented in Ref. [35] where they are mediated by SM gauge boson and Higgs.

When LHT effects are included the branching ratios become [35]

\[
B_L(0) = B_L(W_H, W_H) + B_L(Z_H, Z_H) + B_L(A_H, A_H) + B_L(A_H, Z_H) + B_L(\Phi, \Phi).
\]

(29)

We can observe the branching ratios of the wrong sign processes vanish. In the following sections we consider Majorana neutrinos in LHT for computing wrong sign processes in order to get non zero results, since it is known that the heavy Majorana masses (in the TeV scale) impact LFV processes [38–40].

5. Inverse seesaw neutrino masses in LHT model

We do an extension of LHT model implementing Majorana neutrinos with an ISS mechanism, you can see more details of this method in [36], the main aspects are shown next.
We need to recall that Yukawa Lagrangian (see Eq. (19)) gives masses at order of $\sim f$, it is written as [12,36]
\[
\mathcal{L}_{Y\mu} = \kappa_{1}f (\bar{\Psi}_{2}\xi + \bar{\Psi}_{1}\Sigma_{0}\xi^\dagger) \Psi_{R}
\]
\[
= \sqrt{2}\kappa_{1}f\bar{\Psi}_{HL}\Psi_{HR} + \cdots ,
\]
where we have approximated $\xi = \exp(i\Pi/f) \approx 1$.

Symmetry allows us to introduce a lepton singlet $\chi_{L}$, which gets mass by combining directly with a RH singlet $\chi_{R}$ through a direct mass term. Thus, its mass term is read
\[
\mathcal{L}_{M} = - M\bar{\chi}_{L}\chi_{R} + h.c.. \tag{31}
\]
Since $\chi_{L}$ is a $SU(5)$ singlet we can include a small Majorana mass for it. We assume LN to be broken by small Majorana masses $\mu$ in the heavy LH neutral sector, then
\[
\mathcal{L}_{\mu} = - \frac{\mu}{2}\bar{\chi}_{L}\chi_{L} + h.c.. \tag{32}
\]
The neutrino mass matrix, which must be T-even, reduces to the inverse see-saw one [36]
\[
\mathcal{M}_{\nu}^{T-even} = \left(\begin{array}{ccc}
\nu_{L}^{i} \\
\chi_{R}^{j}
\end{array}\right) + h.c., \tag{33}
\]
where
\[
\mathcal{M}_{\nu}^{T-even} = i\kappa f \sin \left(\frac{\theta}{\sqrt{2}f}\right) M^{\dagger}.
\]
We recall the ISS hierarchy $\mu \ll \kappa \ll M$. The mass eigenvalues for $M$ are $\sim 10$ TeV, of the order of $4\pi f$ with $f \sim$ TeV, if we assume the $\kappa$ eigenvalues to be order 1. While the $\mu$ eigenvalues are smaller than the GeV.

The mass eigenstates from Eq. (34) are given by
\[
\sum_{j=1}^{3} U_{ij}\nu_{Lj}^{i} = \sum_{j=1}^{3} \left(1_{3\times 3} - \frac{1}{2}[\theta^{\dagger}\theta]\right)_{ij} \nu_{Lj}^{i} - \sum_{j=1}^{3} \theta_{ij}\chi_{Lj}^{j},
\]
\[
\chi_{Li}^{j} = \sum_{j=1}^{3} \left(1_{3\times 3} - \frac{1}{2}[\theta^{\dagger}\theta]\right)_{ij} \chi_{Lj}^{j} + \sum_{j=1}^{3} \theta_{ij}\nu_{Lj}^{i},
\]
where
\[
\theta = - if \sin \left(\frac{\theta}{\sqrt{2}f}\right) M^{\dagger}, \tag{36}
\]
with $U$ denoting the $U_{PMNS}$ matrix. Therefore, the mass matrix $\mathcal{M}_{\nu}^{l}$ for light (active) neutrinos is
\[
(\mathcal{M}_{\nu}^{l})_{ij} = \theta_{ik}\mu_{kl}\theta_{lj}^{\dagger}. \tag{37}
\]
In terms of the mass eigenstates the SM charged currents are modified as follows
\[
\mathcal{L}_{W}^{l} = g \sqrt{2} W^{\mu}_{\mu} \sum_{j=1}^{3} \sum_{i=1}^{3} \bar{W}_{ij}\gamma^{\mu} P_{L} \ell_{j} + h.c., \tag{38}
\]
\[
\mathcal{L}_{W}^{th} = g \sqrt{2} W^{\mu}_{\mu} \sum_{j=1}^{3} \sum_{i=7}^{9} \bar{W}_{ij}\gamma^{\mu} P_{L} \ell_{j} + h.c.,
\]
where $W$ matrix has been defined as
\[
W_{ij} = \{U^{\dagger}[1_{3\times 3} - \frac{1}{2}(\Theta^{1})]\}_{ij}. \tag{39}
\]

And the SM neutral currents become
\[
\mathcal{L}_{Z}^{l} = \frac{g}{2 \cos \theta_{W}} Z^{\mu}_{\mu} \sum_{i,j=1}^{3} \bar{f}_{i}^{\nu} \gamma^{\mu} (Y_{ij} P_{L} - Y_{ij} P_{R}) \nu_{j}^{\dagger}, \tag{40}
\]
\[
\mathcal{L}_{Z}^{th} = \frac{g}{2 \cos \theta_{W}} Z^{\mu}_{\mu} \sum_{i,j=1}^{3} \bar{f}_{i}^{\nu} \gamma^{\mu} (S_{ij} P_{L} - S_{ij} P_{R}) \nu_{j}^{\dagger} + h.c.,
\]
whose neutral couplings turn out to be
\[
X_{ij} = \sum_{k=1}^{3} (U^{\dagger}[1_{3\times 3} - (\theta^{0}\theta^{\dagger})])_{ik} U_{kj}, \tag{41}
\]
\[
Y_{ij} = \sum_{k=1}^{3} \theta_{ik}^{\dagger} U_{kj}, \quad S_{ij} = \sum_{k=1}^{3} \theta_{ik}^{\dagger} \theta_{kj}.
\]
If we compare our charged-current and neutral-current interactions with the SM ones, we observe that they differ by the presence of the $\theta$ matrix which is consequence of introducing Majorana neutrinos.

6. Bounds on LFV processes

Along the calculation we will use ’t Hooft-Feynman gauge. We present two types of LFV processes in this section: $\ell \to \ell'\gamma$ and $\ell \to \ell'\nu\bar{\nu}$, where the last one has three possible channels but we are just focusing on wrong sign processes ($\ell \neq \ell'$ or $\ell' \neq \ell''$) involving Majorana Neutrinos.

6.1. $\ell \to \ell'\gamma$ decays

From Eq. (23) and using $F_{M}^{\gamma} = - i F_{E}^{\gamma}$ the results will be simplified. The contribution coming from light and heavy Majorana neutrinos is
\[
Br(\mu \to e\gamma) = \frac{3\alpha_{1}}{2\pi} \left| W_{ej} W_{\mu j}^{\ast} F_{M}^{X}(X_{j}) \right| + U_{ej}U_{\mu j}^{\ast} F_{M}^{\nu}(y_{j}), \tag{42}
\]
recalling that $U = U_{PMNS}$ and $W$ is given by Eq. (39). For active neutrinos ($m_{\nu_{\mu}} \ll M_{W}$), the $F_{M}^{\nu}(y)$ function, defining $y = m_{\nu_{e}}^{2}/M_{W}^{2}$, yields
\[
F_{M}^{\nu}(y) = \frac{5}{6} - \frac{3y - 15y^{2} - 6y^{3}}{12(1 - y^{3})} + \frac{3y^{3}}{2(1 - y^{3})} \ln y, \tag{43}
\]
\[
\text{Supl. Rev. Mex. Fis. 3 020704}
\]
and for heavy neutrinos ($m_{\chi} \gg M_W$)

$$F_M^X(x) = \frac{1}{3} - \frac{2x^3 - 7x^2 + 11x}{4(1-x)^3} + \frac{3x}{2(1-x)^4} \ln x,$$  \hspace{0.5cm} (44)

with $x = M_W^2/m_{\chi}^2$, being $m_{\chi}$ the mass of heavy Majorana neutrinos.

The branching ratio for $\mu \to e\gamma$ turns out to be

$$\text{Br}(\mu \to e\gamma) \approx \frac{3\alpha}{8\pi} |\theta_{e\mu}\theta^*_{\mu\mu}|^2.$$ \hspace{0.5cm} (45)

By considering the general form for the $\ell \to \ell'\gamma$ decays we do the proper replacements on the Eq. (45). Then, the 90\% C.L. limits $\text{Br}(\mu \to e\gamma) < 4.2 \times 10^{-13}$, $\text{Br}(\tau \to e\gamma) < 3.3 \times 10^{-8}$ and $\text{Br}(\tau \to \mu\gamma) < 4.2 \times 10^{-8}$ [42,43] bind

$$|\theta_{e\gamma}\theta^*_{\mu\mu}| < 0.14 \times 10^{-4}, \quad |\theta_{e\gamma}\theta^*_{\mu\mu}| < 0.95 \times 10^{-2},$$

$$|\theta_{\mu\mu}\theta^*_{\mu\mu}| < 0.011.$$ \hspace{0.5cm} (46)

6.2. Wrong-Sign decays: $\ell \to \ell'\ell''\mu^\pm$ with $\ell' \neq \ell'' \neq \ell''$

These processes have no penguin contributions, only box diagrams are involved, so the decay width of $\ell \to \ell'\ell''\mu^\pm$ is

$$\Gamma(\ell \to \ell'\ell''\mu^\pm) = \frac{\alpha^2M_\ell^5}{192\pi} |F_B|^2,$$  \hspace{0.5cm} (47)

the box diagrams are shown in Fig. 4.

The form factor for each box diagram in Fig. 4 is written as follows

$$F_B^{\nu\nu} = \frac{\alpha W}{16\pi M_W} \sum_{i,j=1}^3 \{W_{i\ell}W_{j\ell'}W_{\ell\nu}\theta_l \theta_{\nu\mu}\},$$

$$F_B^{e\nu} = \frac{\alpha W}{16\pi M_W^2} \sum_{i,j=1}^9 \{W_{i\ell}W_{j\ell'}\theta_l \theta_l\theta_l\theta_{\nu\mu}\},$$

$$F_B^{\chi_h \chi_h} = \frac{\alpha W}{16\pi M_W^2} \sum_{i,j=7}^9 \{\theta_l \theta_l \theta_l \theta_{\nu\mu}\},$$

where the $y_i$ and $x_i$ variables are defined in Subsec. 6.1, whose behavior is $x_i, y_i \to 0$. The $F_B^{\nu\nu}$, $F_B^{e\nu}$, and $F_B^{\chi_h \chi_h}$ functions are Four-Point Functions. The ordinary $f_B^{l\ell}$ function is given by

$$f_B^{l\ell}(y_i, y_j) = \left(1 + \frac{1}{4}y_i y_j\right) \tilde{d}_0(y_i, y_j) - 2y_i y_j d_0(y_i, y_j),$$ \hspace{0.5cm} (51)

where $\tilde{d}_0(y_i, y_j)$ and $d_0(y_i, y_j)$ can be consulted in the Appendix C.3 of [12]. The other functions $f_B^{l\ell}$ and $f_B^{l\ell}$ are obtained straightforwardly by doing the corresponding change of variables.

In addition, we have box diagrams with LNV vertices which are shown in Fig. 5. The form factor due to light neutrinos is

$$F_B^{\nu\nu} = \frac{\alpha W}{16\pi M_W^2} \sum_{i,j=1}^3 \{W_{i\ell}W_{j\ell'}W_{\ell\nu}\} \times f_{B-LNV}^{l\ell}(y_i, y_j).$$ \hspace{0.5cm} (52)

The contributions from diagrams that mix light and heavy neutrino and diagrams that consider just heavy neutrinos are given by

$$F_B^{\ell\ell\ell\mu} = \frac{\alpha W}{16\pi M_W^3} \sum_{i,j=1}^9 \{\theta_l \theta_l \theta_l \theta_{\nu\mu}\},$$

$$F_B^{\ell\ell\ell\mu} = \frac{\alpha W}{16\pi M_W^3} \sum_{i,j=1}^9 \{\theta_l \theta_l \theta_l \theta_{\nu\mu}\},$$

where for the functions $f_B^{l\ell\ell\mu}(z_i, z_j)$, we can apply the same arguments as the previous $f_B^{l\ell\ell\mu}(z_i, z_j)$. Therefore

$$f_{B-LNV}^{l\ell\ell\mu}(y_i, y_j) = \sqrt{y_i y_j} \left(2d_0(y_i, y_j) - (4 + y_i y_j) d_0(y_i, y_j)\right),$$ \hspace{0.5cm} (55)

for $f_{B-LNV}^{l\ell\ell\mu}(z_i, z_j)$ we do the appropriate conversion of variables.

So, the complete form factor reads

$$F_B = F_B^{\nu\nu} + F_B^{e\nu} + F_B^{\chi_h \chi_h} + F_B^{l\ell\ell\mu} + F_B^{l\ell\ell\mu} + F_B^{l\ell\ell\mu}.$$ \hspace{0.5cm} (56)

After considering some approximations ($x_i, y_i \to 0$), we obtained that the branching ratio for wrong sign processes is simplified as follows

![Figure 4. Box diagrams, without Majorana neutrino contributions.](https://example.com/figure4.png)

![Figure 5. Contributions coming from LNV diagrams.](https://example.com/figure5.png)
\[ \text{Br}(\ell \rightarrow \ell'\ell''\mu^m) = \frac{\alpha_W^2}{128\pi^2} \frac{3}{4} \left| \left\{ \theta_{ei}\theta_{i',e}^{*} \theta_{i'}^{*}\theta_{i'}^{*} \right\} \left( \theta_{i'i'} \theta_{i'i'}^{*} \right) \right|^2 \times \frac{1}{x_j} \ln \left( \frac{x_i}{x_j} \right) \]

\[ + \frac{1}{4x_j} \ln \left( \frac{x_i}{x_j} \right) + \frac{1}{4} \left( 6\ln x_j + 7 \right) + \left[ \theta_{i'i'} \theta_{i'i'}^{*} \theta_{i'i'}^{*} \right] \sqrt{\frac{x_i}{x_j}} \ln \left( \frac{x_j}{x_i} \right) + \sqrt{\frac{x_i}{x_j}} (2\ln x_j + 1) \]

\[ + \frac{1}{\sqrt{x_i x_j}} (\ln x_j + 1) + \frac{1}{\sqrt{x_i x_j}} (2\ln x_j + 1) \right|^2. \]  

(57)

From the expression above we could find values for branching ratios of wrong sign processes which are bound

\[ \text{Br}(\tau \rightarrow ee\bar{\mu}) < 1.5 \times 10^{-8} \]

and \[ \text{Br}(\tau \rightarrow \mu\bar{\mu}) < 1.7 \times 10^{-8} \]

(C.L. = 90%) [42].

### 7. Numerical analysis for wrong sign processes

We study two tau decays known as wrong-sign processes:

\[ \tau \rightarrow ee\bar{\mu} \] and \[ \tau \rightarrow \mu\bar{\mu} \].

This analysis is done by a Monte Carlo simulation where both processes are computed simultaneously assuming that the LNV couplings are free parameters, thus we are able to bind them. So we have 9 free parameters for each wrong sign processes which will be: the masses of heavy neutrinos, \( M_i \) that are the same for both processes and the LNV couplings corresponding to each decay:

- \( \tau \rightarrow ee\bar{\mu} \): LNV couplings: \((\theta_{\mu_1}\theta_{\tau_1})^\dagger\), and \(\theta_{i_1}\theta_{\tau_i}\) with \(i = 1, 2, 3\). We bind the couplings as follows [44]

\[ |\theta_{\mu_1}\theta_{\tau_1}| + |\theta_{\mu_2}\theta_{\tau_2}| + |\theta_{\mu_3}\theta_{\tau_3}| < 1.225 \times 10^{-3}, \]

\[ |\theta_{e_1}\theta_{\tau_1}| + |\theta_{e_2}\theta_{\tau_2}| + |\theta_{e_3}\theta_{\tau_3}| < 0.050, \]  

(58)

and their product must satisfy [44]

\[ |\theta_{\mu_1}\theta_{\tau_1}| |\theta_{e_1}\theta_{\tau_1}| < 6.125 \times 10^{-5}. \]  

(59)

Supl. Rev. Mex. Fis. 3 020704
lected data of the Monte Carlo simulation we find that the correlation coefficient between branching ratios is 0.08 which means a practically null correlation.

In the Table III we write down the resulting mean values for each free parameter of this model: three heavy neutrino masses $M_i$, LNV couplings and the branching ratios for both decays. We conclude that in this model branching ratios corresponding to wrong-sign decays are one order of magnitude below the current upper limits. Thus, there are no sizable correlations among heavy neutrino masses (C.L.=90%).

In Table IV we show the mean values for the other LFV processes which are computed simultaneously with a single Monte Carlo simulation since in contrast to wrong sign processes, they share the same free parameters.

We see that the difference among mean values for the heavy neutrino masses from the previous results in Table III and IV is $\sim 3\%$ in all cases.

8. Lepton number violating tau decays

These processes are represented as follows

$$\tau^- (p_{\tau}) \rightarrow \ell^+ (p_{\ell^+}) M_i^- (q_1) M_2^- (q_2),$$

where $M_i^-, M_2^- = \pi, K$.

We consider only tree level amplitude as it is the dominant contribution. Box diagrams are not taken into account. The decay amplitude for lepton number violating tau decays can be separated into leptonic and hadronic parts

$$i\mathcal{M} = (\mathcal{M}_{lep})_{\mu\nu}(\mathcal{M}_{had})^{\mu\nu},$$

where

$$(\mathcal{M}_{lep})_{\mu\nu} = -\frac{g^2}{2} \sum_{i=1}^{3} \tau(p_{\tau}) \left( \frac{W_{\tau i}^2 W_{\ell^+ i} m_i}{k^2 - m_i^2} + \frac{\theta_{\tau i} \theta_{\ell^+ i} M_i}{q^2 - M_i^2} \right) \times \gamma_{\mu} \gamma_{\nu} P_R v(p_{\ell^+})$$

$$+ (M_1 \leftrightarrow M_2),$$

with $m$ and $M$ the masses of light and heavy Majorana neutrinos, respectively. The leptonic part of the subprocess $\tau^- \rightarrow \ell^+ W^- W^+$ is obtained by crossing the $W^- W^- \rightarrow \ell^- \ell^-$ amplitude.

The total amplitude has two contributions: one comes from light neutrinos ($\mathcal{M}_{light}$) and the second one comes from heavy neutrinos ($\mathcal{M}_{heavy}$). The part of light neutrinos is very suppressed due to their masses. Therefore, we work only with heavy neutrinos contribution.

$$\text{Br}(\tau^- \rightarrow e^+ \pi^- \pi^-) < 6.47 \times 10^{-27},$$

$$\text{Br}(\tau^- \rightarrow \mu^+ \pi^- \pi^-) < 5.88 \times 10^{-27},$$

$$\text{Br}(\tau^- \rightarrow e^+ K^- K^-) < 1.01 \times 10^{-29},$$

$$\text{Br}(\tau^- \rightarrow \mu^+ K^- K^-) < 9.19 \times 10^{-30},$$

$$\text{Br}(\tau^- \rightarrow e^+ \pi^- K^-) < 2.73 \times 10^{-28},$$

$$\text{Br}(\tau^- \rightarrow \mu^+ \pi^- K^-) < 2.48 \times 10^{-28}.$$ (71)

We can see that our results obtained by LHT extended with Majorana neutrinos through ISS are much more constrained than the current limits [42]. This was expected because we started from the fact that $M_{\text{heavy}}$ is small due to the masses of the heavy neutrinos. As heavy neutrino masses are of the order of TeVs there is no resonant enhancement.

9. Conclusions

- LHT is not able to bind LFV processes known as “wrong-sign” through T-odd leptons. However, when we extend the LHT model involving Majorana neutrinos with aid of ISS, the branching ratios get a finite value (C.L. = 90%):

$$\text{Br}(\tau \rightarrow e e \bar{\mu}) < 1.483 \times 10^{-9},$$

$$\text{Br}(\tau \rightarrow \mu \mu \bar{e}) < 1.658 \times 10^{-9},$$

which are one order of magnitude more suppressed than the current values [42].

- LHT extended with Majorana neutrinos also allows us to bind the LNV couplings (C.L. = 90%), which have not been reported before in papers as [44]

$$|\theta_{\mu \mu} \theta_{\tau i}| < 13.47 \times 10^{-4}, \quad |\theta_{\tau i} \theta_{\ell^+ i}| < 2.609 \times 10^{-2},$$

$$|\theta_{\ell^+ i} \theta_{\tau i}| < 1.413 \times 10^{-3}, \quad |\theta_{\mu \mu} \theta_{\tau i}| < 2.484 \times 10^{-2}.$$

- The mean values for $\tau \rightarrow \ell \ell' \ell''$ decays and $\mu \rightarrow e$ conversion in Ti obtained in our simulation are one order of magnitude smaller than current limits. In $\mu \rightarrow e e \bar{e}$, $Z \rightarrow \ell \ell$ and conversion in Au, we get mean values around two orders of magnitude smaller than current limits. Unlike above processes, only $Z \rightarrow \mu \bar{e}$ is not a candidate to be probed in the near future as our result is seven orders of magnitude smaller than current limit.

- Due to heavy Majorana neutrino masses are at order of TeVs, semileptonic three body tau decays are very suppressed. Hence, they are not phenomenological interest as there is no “resonant enhancement”.
