Received 6 September 2022; accepted 12 March 2023

In this research, both the standard molar enthalpy of formation in the crystalline phase and in the gas phase of 3-methylglutaric anhydride was calculated from experimental data. The temperature and enthalpy of fusion, as well as the molar heat capacity in solid phase was calculated by differential scanning calorimetry; the molar enthalpy of sublimation at 298.15 K by the Knudsen effusion method, the molar enthalpy of vaporization at 298.15 K by thermogravimetric analysis, and the standard molar combustion energy by combustion adiabatic calorimetry. Since 3,3-dimethylglutaric anhydride presented crystal transitions (with endothermic points at 352.76 K, 356.98 K and 397.15 K), some of its thermochemical properties were estimated from the functional group-contribution methods proposed by Benson, Gani and Naef and from application of Machine Learning based models.

Keywords: 3-methylglutaric anhydride; 3,3-dimethylglutaric anhydride; enthalpy of formation; functional group-contribution methods.
DOI: https://doi.org/10.31349/RevMexFis.69.051701

1. Introduction

Cyclic acid anhydrides have been used as tools for bioconjugation [1], in the field of catalysts [1–6], in food chemistry [7], for cancer immunotherapy [8], in the synthesis of herbicides [9], for the preparation of membranes [10], in the green synthesis of macromolecules and nanoparticles [11, 12], in the polymer and copolymer area [13–15], among other applications. Moreover, some cyclic anhydrides present unusual physical behavior and polymorphic phase transitions in crystalline phase whose properties have been obtained by differential scanning calorimetry and powder X-ray diffraction [16–18]. Thermal and calorimetric analyses have been applied in investigations for material characterizations [19, 20] and on obtaining properties of polymorphic organic compounds based on previously established methodologies [21–23].

The standard molar enthalpies of formation are of the utmost importance since they generally are occupied to determine standard molar enthalpies of reaction and, thus, anticipate the exothermic or endothermic nature of a process [13]. Unfortunately, thermochemical properties of certain compounds cannot be obtained experimentally since they decompose during thermal analysis or, when appropriate, they show different transitions during their heating [24]. Therefore, it is necessary to fall back on the application of functional group contribution methods and machine-learning-based models, procedures useful in chemical engineering [25, 26]. Among cyclic anhydride derivatives whose standard molar enthalpies of formation had not been determined until reported in this research, are 3-methylglutaric and 3,3-dimethylglutaric anhydrides, Fig. 1.

To 3-methylglutaric anhydride (MGA) the melting point, enthalpy of fusion and molar heat capacity in crystal phase, were obtained by differential scanning calorimetry (DSC). The molar enthalpies of sublimation and vaporization at 298.15K were determined by Knudsen effusion method and by thermogravimetric analysis (TGA), respectively. The standard molar enthalpy of formation in gas phase at 298.15K was calculated from the standard molar enthalpy of sublimation and formation in the crystal phase at 298.15K. This value together with the one of glutaric anhydride (GA) [27], were occupied to validate the functional group contribution methods used to estimate some thermochemical properties of 3,3-dimethylglutaric anhydride (DMGA), which showed drawbacks during purification and, therefore, in all its experimental analysis. Finally, a statistical method applying a multiple linear regression model based on machine learning was applied to estimate the enthalpy of formation in gas phase to DMGA.

2. Experimental

2.1. Materials and purity control

MGA [CAS: 4166-53-4] and DMGA [CAS: 4160-82-1] were acquired from Sigma-Aldrich, the mole-fraction purities reported by them were 0.98 and 0.99, respectively. The device used to calculate temperature and molar enthalpy of fusion was a Perkin Elmer DSC7 at a heating rate of 1.0 Kmin⁻¹ and a high purity nitrogen flow of 30.0 cm³min⁻¹ (x = 0.99997 and supplied by Infra Co.), this was calibrated for both temperature and heat flow using Indium metal [CAS: 7440-74-6] provided by NIST with mole fraction purity of 0.999999, fusion enthalpy of 28.6 Jg⁻¹ and melting point of 429.75 K [28–30].

MGA heat capacity was determined by DSC at a heating rate of 10.0 Kmin⁻¹ in a constant flow of nitrogen at 30.0 cm³min⁻¹ from 273.15 K to 304.15 K. The calibration was carried out with aluminum oxide [CAS: 1344-28-1, x = 0.9995] as a standard material provided by NIST, using the “two steps” method [31].

2.2. Combustion calorimetry

A Parr 1341 plain jacket adiabatic calorimeter was used for the combustion experiments, the methodology of this technique has been detailed in previous research [13]. The combustion energy of MGA was determined after calibration with benzoic acid as calorimetric standard of NIST (Standard Material Reference 39), the certified massic energy of combustion of this standard of -(26434.0 ± 3.0) Jg⁻¹ (the uncertainty is the standard deviation of the mean) was corrected from the equation made available by Coops [32]. The energy equivalent of ε(calor)=(9930.1 ± 2.2) JK⁻¹ obtained from five calibration runs was made known in previous work [11], the uncertainty is twice the standard deviation of the average.

The combustion experiments of MGA were performed using a 0.022 L capacity bomb filled with high purity oxygen (x = 0.99996, supplied by Infra. Group) at a pressure of 3.04 MPa. In each test 0.1 cm³ of deionized water was occupied, approximately 1.1 g of MGA, 13.15 g of nichrome (with burning energy of Δ_u=c(nichrome)= -(5857.6 ± 1.0) Jg⁻¹ where the uncertainty is the standard deviation of the average). Besides, 4.184 J of ΔUign were provided by an ignition unit (Parr 2901). The energy of nitric acid formation during combustion was determined by titration, the value used of heat liberated in the formation of 0.1N HNO₃ under bomb conditions was ΔUdec(HNO₃) = −59.7 kJmol⁻¹ [33]. A 6775 Digital thermometer (from 10 to 40°C, inaccuracy: ±0.001°C) was used to measure the temperature, and a digital multimeter HP 34420 A to register the resistance.

The physical properties of some materials were considered to correct ΔUexp (Eq. (1)) to ΔU°(298.15 K) (Eq. (2)). MGA (M = 128.1338 g mol⁻¹ [34], ρ = 1.159 g mL⁻¹ (value calculated using Advanced Chemistry Development (ACD/Labs) Software V11.02 (©1994-2022 ACD/Labs), - (δυ/δp)T =0.200 Jg⁻¹ MPa⁻¹ [35], C_p (cr, 298.15 K)= 1.405 ± 0.104 Jg⁻¹K⁻¹ (experimental average value from two experiments using DSC device. Its uncertainty corresponds to expanded uncertainty with a level of confidence of approximately 95%), benzoic acid (M=122.1220 gmol⁻¹ [34], ρ = 1.320 gmL⁻¹ [35], - (δυ/δp)T =0.115 Jg⁻¹MPa⁻¹ [35], C_p (cr, 298.15 K)=1.209 Jg⁻¹K⁻¹ [35], stainless-steel (ρ = 7.915 gmL⁻¹ (Value provided by Parr for 45C10), - (δυ/δp)T =0.200 Jg⁻¹MPa⁻¹ [35], C_p(cr, 298.15 K)=0.500 Jg⁻¹K⁻¹ (value provided by Parr for 45C10), and nichrome (M = 57.3670 gmol⁻¹ [34], ρ = 8.558 gmL⁻¹ (value provided by Parr for 45C10), - (δυ/δp)T =0.200 Jg⁻¹MPa⁻¹ [35], C_p(cr, 298.15 K)=0.450 Jg⁻¹K⁻¹ (value provided by Parr for 45C10)).

\[
\Delta U^\text{exp} = -[\varepsilon(\text{calor})(-\Delta T) + \Delta U_{\text{dec}}(\text{HNO}_3) + \Delta U_{\text{ign}}] + m(\Delta_u)(\text{nichrome}),
\]

(1)

\[
\Delta_c U^p(298.15 K) = -(m\Delta_u)(298.15 K) = \Delta U^\text{exp},
\]

(2)

\[-\varepsilon(\text{cont})(-\Delta T) - \Delta U_{\text{cont}} - \varepsilon(\text{cont})(-\Delta T) = \varepsilon f(298.15 K - T_f + \Delta T_{\text{corr}}) + \varepsilon i(T_i - 298.15 K),
\]

(3)

where ε(∂cont) is bomb content energy (Eq. (3)), ε(∂cont) and ε f(∂cont) are the energy equivalents of the bomb contents in the initial and final states, T_i and T_f are the initial and final temperatures of experiment and ΔU_{corr} is the correction to standard state.

2.3. Thermogravimetry using the Langmuir method

To estimate the enthalpy of vaporization, the procedure described by Price [36] applying the Langmuir equation was used:

\[
(dm/dt)(1/A) = p \cdot \alpha(M/2\pi RT)^{1/2},
\]

(4)

where (dm/dt) is the rate of mass loss, A is the vaporization area, p is the vapor pressure, T is the absolute temperature, M is the molar mass, R is the gas constant, and α is the vaporization coefficient (equivalent to 1 when it comes to macromolecules or under vacuum conditions).

One way to determine the enthalpy of phase change from the vapor pressure is by combining the Langmuir and Clausius-Clapeyron equations, so that the Eq. (5) is obtained:

\[
\ln(dm/dt)(1/A)(T/M)^{1/2} = C - (\Delta L^p H_m)(1/T),
\]

(5)

where C groups the involved constants and ΔL^p H_m is the enthalpy of vaporization at average temperature T_m. For this investigation, as the loss of mass occurs after the melting temperature, the vaporization enthalpy was determined directly from the analysis of the MGA thermogram at T_m and later corrected to 298.15 K.

Rev. Mex. Fis. 69 051701
A TA instruments SDT 600 TGA/DSC was used for this procedure, its characteristics are reported in the literature [37]. The device calibration was performed for mass, temperature, and enthalpy of vaporization. Mass calibration was carried out with a standard provided and certified by the NIST as (315.162 ± 0.0048) mg. Temperature and heat flow calibration was carried out with high purity indium, this standard presents a NIST certified temperature of (315.08 K ± 0.00044) K and enthalpy of fusion of (28.51 ± 0.19) Jg⁻¹. During the calibrating was obtained a k (calibration constant) of 1.0000, determined from the fusion enthalpy. The nitrogen flow of 100 cm³ min⁻¹ and heating rate of 10 Kmin⁻¹ were obtained by different experimental tests with pyrene [CAS: 129-00-0, x = 0.9996 ± 0.0003] and phenanthrene [CAS: 85-01-8, x = 0.9997 ± 0.0001]. The vaporization enthalpy of (89.5 ± 1.4) kJmol⁻¹ to pyrene and (79.5 ± 1.4) kJmol⁻¹ to phenanthrene were compared with those reported in the literature, obtaining approximate values.

2.4. Knudsen effusion method

Another way to calculate the vapor pressure from the rate of mass loss was through the Knudsen effusion equation:

\[ p = \left( \frac{\Delta m}{\Delta t} \cdot \frac{w_0 A_0}{w_0 A_0} \right) \left( \frac{2\pi RT}{M} \right)^{1/2}, \]  

(6)

where \( \Delta m/\Delta t \) is the rate of mass loss, \( T \) is absolute temperature, \( w_0 \) is the Clasing probability factor, \( A_0 \) is the effusion area, \( R \) is the ideal gas constant, and \( M \) is the molar mass.

Equation (7) obtained by combining the previous expression with the Clausius-Clapeyron equation, allowed to determine the enthalpy of sublimation \( \Delta H_m \), the details of experimental method have been described in previous studies [36].

\[ \ln\left(\frac{\Delta m}{\Delta t}\right) \cdot T^{1/2} = \ln\left(\frac{1}{w_0 A_0}\right) \left(\frac{2\pi R}{M}\right) \]  

\[ - \left( \frac{\Delta H_m}{\pi \rho R / M} \right) \left( \frac{1}{T} \right), \]  

(7)

The rate of mass loss (\( \Delta m/\Delta t \)) at constant temperature was determined from 300.66 K to 306.54 K with steps of 2.0 K and using a vacuum pressure of 10⁻⁶ Torr, this value was utilized to calculate the enthalpy of sublimation. The experiments were carried using aluminum cells with a silver pierced disk whose measures were: Cell A (diameter: 1.345 mm, \( A_0 \): 1.42 mm², thickness: 0.150 mm, \( w_0 \) factor: 0.9228), Cell B (diameter: 1.031 mm, \( A_0 \): 0.835 mm², thickness: 0.135 mm, \( w_0 \) factor: 0.9106), Cell C (diameter: 0.842 mm, \( A_0 \): 0.557 mm², thickness: 0.135 mm, \( w_0 \) factor: 0.8927) and Cell D (diameter: 0.489 mm, \( A_0 \): 0.188 mm², thickness: 0.170 mm, \( w_0 \) factor: 0.7932). The temperature was recorded with a Hart Scientific thermistor model A1143-01 connected to an Agilent multimeter model 34420A. Two VARIAN vacuum pumps (model DS102 and V70D) were used to create a pumping system. The method validation was carried out by determining the sublimation enthalpy of two standards, ferrocene [CAS: 102-54-5, x = 0.9997 ± 0.0003] and anthracene [CAS: 120-12-7, x = 0.9998 ± 0.0003], whose experimental values were (73.4 ± 2.2) kJmol⁻¹ and (104.2±3.2) kJ mol⁻¹, respectively. The experimental values were approximate to those reported in the literature [39–49].

2.5. Estimation methods by contribution of functional groups

Since the enthalpy of formation in both gas and crystalline phases of the compound DMGA could not be determined experimentally due to the presence of three endothermic signals (at 352.76 K, 356.98 K and 397.15 K) before and after purification, three estimation methods proposed by Gani [50], Benson [51–53] and Naef [54, 55] were used to calculate the enthalpy of formation. The method validation was carried out from properties estimation of cyclic acid anhydrides derivatives, including GA and MGA. The procedure has already been described in detail by this research group [11].

Gani’s method [50] separates the functional groups of each molecule into different orders (first, second and third order). This method requires using a \( H_{f0} \) value (42.2361 kJ mol⁻¹) for the estimated enthalpy of formation in gas phase. Benson’s method [51–53] allows to estimate the enthalpy obtaining a theoretical value by locating the different atoms within a molecule (except for hydrogen) and by observing which atom is bonded to the one being studied, for the case of cyclic molecules, it is necessary to introduce a ring strain correction factor (rsc). In Naef’s method [54, 55] the enthalpy of formation in the crystalline phase is made from the enthalpy of combustion, and the estimated enthalpy of formation in the gas phase is calculated from sublimation enthalpy.

2.6. Theoretical results using statistical algorithms

One way to find theoretical values of enthalpy of formation in the gas phase, is applying statistical methods, these methods allow the interpretation of experimental results from another point of view, for this purpose machine learning algorithms were used [56].

2.6.1. Multiple linear regression

This regression model is characterized by the inclusion of multiple regressor variables, in other words, the dependent variable is not affected by only one independent variable. The expression representing this adjustment is presented below.

\[ y = a_0 + a_1 X_1 + a_2 X_2 + ... + a_n X_n \]  

(8)

The model relates a dependent variable with \( n \) regressor variables (\( X_n \)) and finally a random variable (\( a_0 \)) that collects all those factors that are not collectable and are associated to change [57].

Rev. Mex. Fis. 69 051701
2.6.2. Ridge regression

Ridge regression is a popular parameter estimation method used to address the collinearity problem frequently arising in multiple linear regression [58]. The expression representing this adjustment is presented below.

\[ RSS_{\text{Ridge}} = \sum_{i=1}^{n} (y_i - f(x_i))^2 + \frac{1}{2} \lambda \sum_{j=1}^{p} \beta_j^2 \]  
(9)

where \( \lambda \) is a parameter that controls the degree of penalty: the higher the penalty, the lower the coefficients, the more robust to collinearity. When \( \lambda \) is equal to zero, Ridge is equivalent to linear regression.

2.6.3. Lasso regression

LASSO (Least Absolute Shrinkage and Selection Operator) regression aims to identify the variables and corresponding regression coefficients that lead to a model that minimizes the prediction error. This is achieved by imposing a constraint on the model parameters, which ‘shrinks’ the regression coefficients towards zero, that is by forcing the sum of the absolute value of the regression coefficients to be less than a fixed value (\( \lambda \)) [59]. The expression representing this adjustment is presented below.

\[ RSS_{\text{Lasso}} = \sum_{i=1}^{n} (y_i - f(x_i))^2 + \lambda \sum_{j=1}^{p} |\beta_j|, \]  
(10)

where \( \lambda \) is a parameter that controls the degree of penalty: the higher the penalty, the lower the coefficients, the more robust to collinearity. When \( \lambda \) is equal to zero, Lasso is equivalent to linear regression.

3. Results and discussion

From three experiments of MGA the molar fraction, the temperature and molar fusion enthalpy, as well as heat capacity were determined by using DSC device. The molar fraction of MGA after recrystallization from ethyl ether had an average value of \( (0.9996 \pm 0.0001) \). The values obtained to temperature and molar fusion enthalpy were of \( (316.05 \pm 0.01) \) K or \( (42.9 \pm 0.01) \) °C and \( (15.75 \pm 0.37) \) kJ mol\(^{-1} \), respectively, and heat capacity as a function of the temperature in the range from 273.15 K to 304.15 K was of \( (180.0 \pm 13.2) \) J mol\(^{-1}\)K\(^{-1}\). The results showed an uncertainty of 0.95 and corresponds to the expanded uncertainty. To DMGA, even enough and various purification tests using different solvents in each one were done, three endothermic signals appeared at 352.76 K (79.61°C), 356.98 (83.83°C) and 397.15 K (124.0°C), respectively, Fig. 2. Due to these crystal transitions possibly related to the different molecular shape as conformations, conformers or polymorphs neither the temperature nor the enthalpy of fusion could be determined from this technique.

Table I shows the data and average value of \( \Delta_fu^\circ \) (MGA) at 298.15 K of five combustion experiments, the standard molar energy and enthalpy of combustion calculated from this was \( \Delta_fU_m^\circ \) (298.15 K) = \( -(2850.2 \pm 1.9) \) kJ mol\(^{-1} \) and \( \Delta_fH_m^\circ \) (298.15 K) = \( -(2851.4 \pm 1.9) \) kJ mol\(^{-1} \), respectively (where the uncertainty corresponds to the expanded uncertainty of five combustion experiments with confidence level of 95% and include the calibration contributions from benzoic acid and energy of combustion of nichrome thread). Finally, the enthalpy of formation in solid phase of MGA of \( \Delta_fH_m^\circ \) (cr, 298.15 K) = \( -(653.0 \pm 2.1) \) kJ mol\(^{-1} \) was obtained taking into consideration the values of the enthalpies of formation in standard state for H\(_2\)O (l) of \( -(285.83 \pm 0.04) \) kJ mol\(^{-1} \) and for CO\(_2\) (g) of \( -(393.51 \pm 0.13) \) kJ mol\(^{-1} \) [58] (the uncertainty of \( \Delta_fH_m^\circ \) (cr) corresponds to the expanded uncertainty with confidence level of 95% and includes the uncertainties of standard enthalpy of formation of H\(_2\)O (l) and CO\(_2\) (g)). The idealized reaction occupied is presented in Eq. (11).

\[ \text{C}_6\text{H}_8\text{O}_3\text{(cr)} + 6.5\text{O}_2\text{(g)} \rightarrow 6\text{CO}_2\text{(g)} + 4\text{H}_2\text{O}\text{(l)} \]  
(11)

The rate of mass loss (\( dm/dt \)) in the range of temperature from 339.15 K to 389.15 K was determined by using TGA, and from 300.66 to 306.54 K via Knudsen effusion. From these data, it was possible to obtain the vaporization enthalpy at average temperature of \( T_m = 364.15 \) K and the sublimation enthalpy at \( T_m = 303.42 \) K, respectively. These vaporization and sublimation enthalpies at \( T_m \) were corrected at 298.15 K, using equation series (12) and (13). These values are shown in the Table II (the uncertainties of enthalpies of sublimation and vaporization at \( T_m \) correspond to weighted average at 298.15 K to twice the combined standard).

\[ \Delta_f^\circ H_m(298.15K)/\text{kJ} \cdot \text{mol}^{-1} = \Delta_f^\circ H_m(364.15K) + \{10.58 + 0.26 \cdot [(0.85C_{p,m}(cr, 298.15K) + 9.83)/0.74/J \cdot \text{mol}^{-1} \cdot \text{K}^{-1}]\} \]
\[ /1000 \cdot (364.15\text{ K} - 298.15\text{ K}) \]  
(12)

Average value Δu^ε(MGA)/kJ g^{-1} = -22.2439 ± 0.0163

Data from five representative experiments where the specific energies of combustion at 298.15 K and 0.1 MPa are displayed, m represents the mass of MGA, stainless steel, and nichrome, the masses were corrected for buoyancy using densities of each one; T_f and T_i are the initial and final temperatures of the experiment, ΔT_{corr} is a correction term, ΔT_{ad} is the corrected temperature rise calculated by ΔT_{ad} = T_f - T_i - ΔT_{corr}; ε(calor) represents the energy equivalent of the entire system, ε(α) and ε(β) are the energy equivalents of the bomb contents in the initial and final states, respectively; ε(cont) is bomb content energy calculated by ε(α)(-ΔT_i) + ε(β)(cont)(T_f - 298.15 K) + ε(γ)(cont)(298.15 K - T_f + ΔT_{corr}); ΔU_{ign} is the ignition energy, ΔU_{dsc}(HNO_3) is the experimental energy of formation of nitric acid, ΔU_{exp} is the energy of the experimental bomb process, which was calculated by ΔU_{exp} = [ε(calor)(-ΔT_i) + ΔU_{dsc}(HNO_3) + ΔU_{ign}(-mΔu^ε(nichrome))], ΔU_{cor} is the correction to standard state and Δu^ε(MGA) is the compound mass energy of combustion. Its uncertainty corresponds to expanded uncertainty with a confidence level of 0.95 approximately.

\[ \Delta_{cr}^g H_m(298.15 \text{ K}) = \Delta_{cr}^g H_m(T_{bas}/K) + \{0.75 + 0.15[C_p,m(c_r, 298.15 \text{ K})/J \cdot \text{mol}^{-1} \cdot \text{K}^{-1}] \} \]

\[ \times \{1000 \cdot \left( T_{fus,Y} - 298.15 \right) - \{10.58 + 0.26[C_p,m(l, 298.15 \text{ K})]/J \cdot \text{mol}^{-1} \cdot \text{K}^{-1}] \} \]

\[ \times \{T_{bas}/K - 298.15 \text{ K}\}. \]  

To determine the enthalpy of formation in gas phase at 298.15 K of \((571.1 ± 4.0) \text{ kJ mol}^{-1}\) the Eq. (15) was applied, the value occupied of sublimation enthalpy was via Knudsen effusion where solid-gas equilibrium can be guaranteed. The uncertainties correspond to the expanded uncertainty with a level of confidence of approximately 0.95.

\[ \Delta_f H_m(g, T) = \Delta_f H_m(c_r, T) + \Delta_{cr}^g H_m(T), \]  

where \(T\) represents the temperature at 298.15 K.

Table IV shows the functional groups and the frequency of appearing for MGA and DMGA, these data were applied to the three estimating methods.

From Tables V to VIII the estimate values obtained by the functional group-contribution methods proposed by Benson, Gani and Naef, are shown. Tables V to VI present the values of vaporization, sublimation and combustion enthalpy obtained by Naef’s method. To apply it in the estimated enthalpy of vaporization, a correction to O-C$(2\pi)$ group was recalculated from the subtraction between the experimental vaporization enthalpy and the theoretical vaporization enthalpy of each anhydride (without considering the recalculated group). Finally, the recalculated average value of 6.0 kJmol$^{-1}$ was applied to estimate the vaporization enthalpy of all cyclic anhydrides. It was observed that the vaporization, sublimation, and combustion estimated enthalpies had an average error of 6.4 kJmol$^{-1}$, 14.3 kJmol$^{-1}$ and 13.6 kJmol$^{-1}$, respectively. Considering the above values to DMGA a vaporization enthalpy of (57.8 ± 6.4) kJmol$^{-1}$, a sublimation enthalpy of (97.8 ± 14.3) kJmol$^{-1}$ and a combustion enthalpy of $-(3495.3 ± 13.6)$ kJmol$^{-1}$, were estimated.

For the estimation of the enthalpies of formation in both gas and crystalline phases by the Benson’s method [51–53], the rsc of maleic anhydride had to be calculated because it is not reported, the value obtained was 16.7 kJmol$^{-1}$ for the gas phase and 19.7 kJmol$^{-1}$ for the crystalline phase. A new GAV value was obtained [53] for the rsc cyclopentane because the reference [51] does not consider whether cyclopentane has radicals or not, likewise the reference [52] does not contain a value of rsc cyclopentane for the crystalline phase. The values used were 19.55 kJmol$^{-1}$ for the gas phase and 34.0 kJmol$^{-1}$ for the crystalline phase. Subsequently these values were used for the estimation of the compound 3,3-Tetramethyleneglutaric anhydride.

Table VII shows the results of enthalpy of formation in crystalline phase to DMGA calculated by Benson and Naef methods. Benson’s method obtained a value of $-(688.7 ± 3.7)$ kJmol$^{-1}$ while Naef method a value of $-(688.5 ± 13.6)$ kJmol$^{-1}$.

Finally, in Table VIII are exposed the estimated enthalpies of formation in gas phase to DMGA by Benson, Gani, and Naef methods, obtaining values of $-(602.3 ± 4.2)$ kJmol$^{-1}$, $-(579.1 ± 8.0)$ kJmol$^{-1}$, and $-(590.7 ± 17.2)$ kJmol$^{-1}$, respectively.
Another way to estimate the enthalpy of formation in gas phase of DMGA was using the enthalpic contribution of the methyl group of gas phase of DMGA was using the enthalpic contribution of methyl group of molecules studied in this work. The database created contains a total of 70 organic compounds divided between carboxylic acids and acid anhydrides, since an anhydride is a derivative of an acid, it can be considered that their molecular interactions are similar, each existing organic compound within the database contains its respective enthalpy of formation in the gas phase.

A multiple Linear Regression, Ridge Regression and Lasso Regression models were applied in order to predict the enthalpy of formation in the gas phase based on the number of carbon, hydrogen and oxygen atoms, the originally created set was divided into two (training and test) with a value of 0.7 and 0.3 respectively and a seed was used to ensure that the results can be repeatable, likewise the evaluation metrics used to determine the effectiveness of the model were the coefficient of determination (R\(^2\)) whose methodology has already been explained previously [73], the root mean square error (RMSE) [74] and the mean absolute error (MAE) [75], likewise a cross validation (K-fold) [76] was applied to the training set in order to know its accuracy. The results, as well as the adjustment equation are presented in Table IX.

In the case of the hyperparameter Alpha present in both the Ridge Regression and the Lasso Regression during Python programming, a for loop was performed in order to evaluate the optimal value for this parameter, it was found that for both regressions the optimal value for alpha is in the interval of (0,2] because after 2 the value of the coefficient of determination begins to decay and 0 cannot be taken because it would become a multiple linear regression, for this work the value used in both cases was Alpha = 2.

![Graphs showing fits for different types of regression.](image-url)

**Figure 4.** Comparison between true and predicted enthalpy of formation values.

Figure 4 shows the fits obtained using the different types of regression for both the training and test sets, as it can be seen the multiple linear regression and the lasso regression were the ones that had the best fit to the data set, the r² value refers to the coefficient of determination between the true data set and the predicted data set.

Based on the metrics shown in Table IX, the types of regression that present a better adjustment in general are Lasso Regression and Multiple Linear Regression, therefore, both adjustment equations will be used to predict the enthalpy of formation of DMGA. Since the equation presented in Table IX do not distinguish between isomerism, it is necessary to introduce a correction factor, this factor was taken from the literature of the Benson type estimation method [53], the value considered was the quaternary -CH₃ correction in order to ensure that both methyl groups are attached to the same carbon atom. Using the equations presented in Table IX, the value of the enthalpy of formation in the gas phase of MGA gives a result of -ΔfH⁰(MGA, g) = 580.3 kJ·mol⁻¹ using the Lasso Regression, -ΔfH⁰(MGA, g) = 576.5 kJ·mol⁻¹ using the Ridge Regression and -ΔfH⁰(MGA, g) = 582.4 kJ·mol⁻¹ using the Multiple Linear Regression, comparing the values with the experimental value, shows a difference of 9.2 kJ·mol⁻¹, 5.4 kJ·mol⁻¹ and 11.3 kJ·mol⁻¹ using the
Lasso Regression, Ridge Regression and Multiple Linear Regression respectively, and DMGA gives as a result of $-\Delta fH^\circ(DMGA, g) = 603.7 \text{ kJmol}^{-1}$ using the Lasso Regression, $-\Delta fH^\circ(DMGA, g) = 599.0 \text{ kJmol}^{-1}$ using the Ridge Regression and $-\Delta fH^\circ(DMGA, g) = 606.0 \text{ kJmol}^{-1}$ using the Multiple Linear Regression, the value of the correction factor is $-4.56 \text{ kJmol}^{-1}$, this factor was applied twice due to the two methyl groups attached to the quaternary carbon, the final values result in $-\Delta fH^\circ(DMGA, g) = 596.9 \text{ kJmol}^{-1}$, $-\Delta fH^\circ(DMGA, g) = 589.9 \text{ kJmol}^{-1}$ and $-\Delta fH^\circ(DMGA, g) = 596.9 \text{ kJmol}^{-1}$ with the Lasso Regression, Ridge Regression and the Multiple Linear Regression, respectively. Comparing the values with the one obtained in the Benson, Gani, and Naef functional group-contribution methods applied to calculate the enthalpies of phase change and formation in both the gas phase and the crystalline phase. Likewise, the standard molar enthalpy of formation was estimated in gas phase of DMGA from two ways 1) from enthalpic contribution of methyl group on GA and on MGA, and 2) from different linear regression algorithms applying Machine Learning. As it can be seen, the estimated enthalpy of formation in gas phase obtained by all methods, the differences between the values gathered fall within uncertainty. With regards to the estimated enthalpy of formation in crystalline phase, the values were very close by both the Benson and Naef method.

4. Conclusions

Some thermochemical properties of MGA were determined by applying differential scanning calorimetry, thermogravimetric analysis, and Knudsen’s effusion method. Since DMGA could not be studied experimentally due to the existence of crystal transitions possibly related to the different molecular shape as conformations, conformers or polymorphs, the Benson, Gani, and Naef functional group-contribution methods were applied to calculate the enthalpies of phase change and formation in both the gas phase and the crystalline phase. Likewise, the standard molar enthalpy of formation was estimated in gas phase of DMGA from two ways 1) from enthalpic contribution of methyl group on GA and on MGA, and 2) from different linear regression algorithms applying Machine Learning. As it can be seen, the estimated enthalpy of formation in gas phase obtained by all methods, the differences between the values gathered fall within uncertainty. With regards to the estimated enthalpy of formation in crystalline phase, the values were very close by both the Benson and Naef method.
