Recibido el 11 de agosto de 1994; aceptado el 23 de enero de 1995

ABSTRACT. The optimal values of absorption energy of F-center for all alkali halides are calculated by using Bartram et al. method. We give the relations between the optical absorption energies and the α parameter for wave functions of type II and type III. These relations are valid only for compounds with larger cations.

RESUMEN. Calculamos los valores óptimos para las energías de absorción de centros F para todos los halogenuros alcalinos utilizando el método de Bartram et al. Proporcionamos las relaciones entre las energías de absorción óptica y el parámetro α para las funciones de onda tipo II y tipo III. Estas relaciones sólo son válidas para compuestos con cationes grandes.

PACS: 71.55; 78.50

1. INTRODUCTION

Theoretical calculations on electron excess color centers, including ion-size effects using Bartram, Stoneham and Gash method [1], and Gourary and Adrian [2] trial wave functions, have been made by many authors. Based in that method [2], we have studied the optical absorption of F and FA-centers in CsF [3] and in KCl:KBr [4], as well as the optical absorption of F-centers in mixed crystals [5].

Recently, we presented the correct expression of the energy functional for the Gourary and Adrian [2] wave function of type II and the calculations for all alkali halides [6] with α = 0.53. Further, not only we have calculated the Z₁ band in RbCl crystals with Mg⁺⁺, Ca⁺⁺, Sr⁺⁺ and Ba⁺⁺ impurities [7] and in other alkali halides [8], but also the F₄-center in KCl:Ca²⁺ [9], using Gourary and Adrian [2] trial wave functions and Gaussian function that proposed by Ong and Vail [10]. Bartram et al. [1] found that good agreement with experimental F-center transition energies could be obtained if all calculated parameter Aγ were reduced in magnitude by a factor α = 0.53. In the case of the FA-center Weber and Dick [11] found that the factor α = 0.53 gave absorption splitting in the wrong direction. When they set α = 1, qualitative agreement with experiment was obtained.

Gash [12] showed that α parameter described the variation in the F-center (or another color center) wave functions across the ion cores. In this way, α should be close to unity for very compact core functions. A factor α = 0.53 would be appropriate for diffuse ions. E.R. López-Téllez et al. [5] have calculated Aγ and Bγ for mixed crystals. The parameter Aγ, which is multiplied by α, is function of the ion radii which form the crystal. Since the α parameter is different for compact and diffusive wave functions, α can be a function
of the interionic distance. Furthermore, from the Mollow-Ivey experimental relation, we know that the optical absorption energy is a function of the interionic distance.

The purpose of the present work is to show the relation between the optical absorption energy and the $\alpha$ parameter which influences in the ion-size correction, and which of Gourary and Adrian's functions [2] describes with more precision the behavior of F-center in alkali halides crystals using the Bartram et al. method [1].

2. THEORY

Only the trial wave functions corresponding to Gourary and Adrian [2] of types II and III are reported here, since we did not obtain good results for function type I.

Following Gourary and Adrian [2] the point-ion potential is

$$V_{PI}(r) = \sum_{x_i'y_i'z_i'=\infty} (-1)^{x_i+y_i+z_i} \left( (x - ax_i)^2 + (y - ay_i)^2 + (z - az_i)^2 \right)^{-1/2}; \quad (1)$$

the prime on the summation sign means that the point $(0,0,0)$ is not considered, $a$ is the interionic distance.

In order to solve the problem of the F-center, we must determine the orbital $\Psi_n$ which minimizes the functional

$$E = \int \{ \Psi^*(r) \left[ \frac{1}{2} \nabla^2 + V_{PI}(r) \right] \Psi(r) \} \, dr \quad (2)$$

subject to

$$\int |\Psi(r)|^2 \, dr = 1. \quad (3)$$

For the ground state $(g)$ and excited state $(e)$ wave functions are

$$\Psi_g^{II} = \begin{cases} A j_0(\xi r/a) \exp(-\eta), & r < a, \\ A j_0(\xi) \exp(-\eta r/a), & r > a, \end{cases} \quad (4)$$

where

$$\eta = 1 - \xi \cot \xi; \quad (5)$$

$$\Psi_e^{II} = \begin{cases} A' j_1(\xi' r/a) \exp(-\eta'), & r < a, \\ A' j_1(\xi')(r/a) \exp(-\eta' r/a), & r > a; \end{cases} \quad (6)$$

where

$$\eta' = 3 - \xi'^2(1 - \xi' \cot \xi')^{-1}; \quad (7)$$
\[
\psi_{\text{III}} = \begin{cases} 
A j_0(\xi r/a) k_0(\eta), & r < a, \\
A j_0(\xi k_0(\eta r/a), & r > a,
\end{cases}
\]  
where
\[
\eta = -\xi \cot \xi
\]  
and
\[
k_0(x) = \frac{1}{x} \exp(-x);
\]  
\[
\psi_{\text{III}} = \begin{cases} 
A' j_1(\xi' r/a) k_1(\eta'), & r < a, \\
A' j_1(\xi' k_1(\eta' r/a), & r > a,
\end{cases}
\]  
where
\[
\eta' = f(\xi') + \left\{ [f(\xi')]^2 + 2 f(\xi') \right\}^{1/2}
\]  
and
\[
f(\xi') = \frac{1}{2} \xi'^2 (\xi' \cot \xi' - 1)^{-1},
\]  
\[
k_1(x) = \left( \frac{1}{x} + \frac{1}{x^2} \right) \exp(-x).
\]  

Here \(A\) and \(A'\) are the normalizing constants, \(\xi\) and \(\xi'\) are the variational parameters, \(j_n(x)\) and \(k_n(x)\) are the spherical Bessel function and the modified spherical Hankel function of order \(n\) respectively.

For Bartram et al. model [1], the pseudopotential \(V_P\) is
\[
V_P = V_{\text{pl}} + \sum_i \left( A_i + (\bar{V}_P - U_i) B_i \right) |\Psi(r_i)|^2,
\]  
where \(U_i\) is the potential of the \(i\)-th ion due to all other ions, \(\bar{V}_P\) is the expectation value of \(V_P\), and \(A_i\) and \(B_i\) are the characteristics parameters of the ions alone.

Finally, including kinetic energy \(T\), the functional for F-center energy has the form
\[
E = T + \bar{V}_{\text{pl}} + \sum_i \left( A_i + (\bar{V}_P - U_i) B_i \right) |\Psi(r_i)|^2.
\]  

Then, the corresponding energy functional are for ground state
\[
E_{\text{II}}^{\text{II}} = \frac{1}{2 a^2} \left\{ \xi^2 - \frac{G(\xi)}{\eta} \left[ \eta^2 - 3 \eta - \frac{1}{2} + \xi^2 \left( 1 - \frac{1}{\eta} + \frac{1}{2 \eta^2} \right) \right] \right\}
\]  
\[- \frac{1}{a} \left\{ \alpha_m - \frac{1}{2} \frac{G(\xi)}{\eta^3} \sum_{x_i \geq y_i \geq z_i \geq 0} \bar{h}_i (-1)^{x_i+y_i+z_i} \left( 1 + \rho_i \xi \right) \frac{1}{\rho_i} \exp \left( -2 \eta (\rho_i - 1) \right) \right\},
\]  
\(i = 1, 2, 3\).
where
\[ [G(\xi)]^{-1} = \left[ 1 - \frac{1}{2\xi} \text{sen} 2\xi \right] (\text{sen} \xi)^{-2} + \frac{1}{\eta} \left( 1 + \frac{1}{\eta} + \frac{1}{2\eta^2} \right), \]  
(19)

\( \alpha_M \) is the Madelung constant; the prime on the summation sign means that the point \((0, 0, 0)\) is omitted and

\[ h_i = \left( \frac{3!}{n_i!} \right) 2^{3-n_i}, \]  
(20)

where \( n_i \) is the number of times any given number occurs in the triplet \((x_i, y_i, z_i)\), and \( 0_i \) is the number of times that zero occurs in this triplet,

\[ \rho_i = (x_i + y_i + z_i)^{1/2} \]  
(21)

\[ E^\text{III}_e = \frac{1}{2a^2} \frac{\xi^2 \eta}{1 + \eta} - \frac{1}{a} \left\{ \alpha_M + \frac{2\eta \xi^2}{(1 + \eta)(\xi^2 + \eta^2)} \right\} \left\{ \sum_{z_i \geq y_i \geq x_i \geq 0} h_i (-1)^{x_i+y_i+z_i} \left( \frac{1}{2\eta \rho_i} \exp[-2\eta(\rho_i - 1)] + \exp(2\eta) E_i(-2\eta \rho_i) \right) \right\}. \]  
(22)

For the excited state,

\[ E^\text{II}_e = \frac{1}{2a^2} \left\{ \xi'^2 - 2G'(\xi') \left[ \frac{\xi'^2 + \eta'^2}{(2\eta')^5} [(2\eta')^4 + 4(2\eta')^3 \right. \right. \]
\[ + 12(2\eta')^2 + 24(2\eta') + 24] - \frac{1}{2(2\eta')^5} [(2\eta')^3 + 3(2\eta')^2 + 6(2\eta') + 6] \right\} \]
\[ - \frac{1}{a} \left\{ \alpha_M - \frac{G'(\xi')}{2\eta'^5} \sum_{z_i \geq y_i \geq x_i \geq 0} h_i (-1)^{x_i+y_i+z_i} \frac{1}{\rho_i} \right. \]
\[ \left. \exp[-2\eta'(\rho_i - 1)] [3 + \frac{3}{2} \eta' \rho + 3(\eta' \rho)^2 + (\eta' \rho_i)^3] \right\}, \]  
(23)

where

\[ [G'(\xi')]^{-1} = 1 - \frac{j_0(\xi')j_2(\xi')}{j_1(\xi')^2} \]
\[ + \frac{1}{2(2\eta')^5} [(2\eta')^4 + 4(2\eta')^3 + 12(2\eta')^2 + 24(2\eta') + 24], \]  
(24)
\[
E_{e}^{\text{III}} = \frac{1}{2a^2} \left[ \xi'^2 - \frac{G'((\xi'))}{\eta'^2} \left(1 + \eta' + \frac{2}{2}(\xi'^2 + \eta'^2) \right) \right] \\
- \frac{1}{a} \left\{ \alpha_{m} - G'((\xi')) \sum_{x_i \geq y_i \geq z_i \geq 0} h_i (-1)^{x_i+y_i+z_i} \right\} \left[ \exp(2\eta' [E_i(-2\eta' \rho_i)]) - \frac{1}{2(\eta' \rho_i)^{2}} (\eta' \rho_i - 1) \exp[-2\eta' (\rho_i - 1)] \right] \}, \quad (25)
\]

where
\[
[G'((\xi'))]^{-1} = \frac{1}{\eta'^{2}} [1 + (\eta'/2)]
\]

\[
+ \left( 1 + \frac{1}{\eta'} \right) \left\{ \frac{1}{[\xi' j_{1}(\xi')]} \left[ \frac{1}{2} \left( 1 + \frac{\text{sen} 2\xi'}{2\xi'} \right) - j_{0}((\xi'))^{2} \right] \right\}. \quad (26)
\]

3. Optimal \(\alpha\) Parameter

Bartram et al. [1] introduced a factor \(\alpha\) in Eq. (17), so the expression with that correction is
\[
E = \tilde{T} + \tilde{V}_{P} + \sum_{\gamma} (\alpha A_{\gamma} + (\tilde{V}_{P} - U_{\gamma}) B_{\gamma}) |\Psi(r_{\gamma})|^{2}. \quad (27)
\]

We found the value of \(\alpha\) that gives the optimal absorption energy for F-center.

Tables I and II show the optimal values of \(\alpha\) for which the theoretical absorption energy is closer to the experimental energy of F-center for all alkali halides. In Table III we can observe the error between the theoretical energy and experimental energy functions type I and III functions. The highest error from experimental values is 1.32% for LiCl using function type II and 3.54% for function type III.

4. Relation between Absorption Energy of F-Center and \(\alpha\) Parameter

The ion size correction takes into account characteristic parameters of the ions, the parameter \(A_{\gamma}\) is reduced in magnitude by a \(\alpha\) factor, we found [6] that \(\alpha = 0.53\) gives a good agreement with experimental results using Gourary and Adrian [2] function type II, and we wondered, what the relation between the interionic distance \(a\) and parameter \(\alpha\) is, and if has an influence on the theoretical energy.

The results from Tables I and II show that for some alkali halides a relation of the following form exists:
\[
\alpha = B a^{m}, \quad (28)
\]

here \(a\) is the interionic distance, \(B\) and \(m\) are constants.
### TABLE I. Optimal parameters \( \alpha, \xi \) and \( \xi' \), and values of ground state energy \( (E_g) \) and energy from excited state \( (E_e) \) for function type II. All energies in u.a.

From Eq. (28) we have

$$a = \left(\frac{\alpha}{B}\right)^{1/m};$$

replacing Eq. (30) in Eq. (29):

$$E_F = C\left(\frac{\alpha}{B}\right)^{-n/m}.\quad (31)$$

Now

$$E_F = D\alpha^x;\quad (32)$$

where

$$D = C\left(\frac{1}{B}\right)^x\quad (33)$$

and

$$x = -\frac{n}{m}.\quad (34)$$

Then, Eq. (32) shows the relation between the absorption energy of F-center and $\alpha$ parameter.

By using a linear regression only with alkali halides in Table IV it is found the values of $C$ and $x$. The correlation for function type II is greater than 0.94, and the mathematical expression is

$$E_F = .0361 \alpha^{-1.927};$$

(35)

and for function type III the correlation is greater than 0.95, and

$$E_F = .03561 \alpha^{-1.927}.$$

(36)

In Figs. 1 and 2 we represented the values obtained for both expressions [Eqs. (35) and (36)].

5. Conclusions

The parameters $A_\gamma$ and $B_\gamma$ are of opposite sign for both types of ion. Furthermore, $B_\gamma$ increases more rapidly than $A_\gamma$ with increasing ionic radius. In compounds with relatively large cations, the ion-size correction adds a net attractive potential cations, the ion-size correction adds a net attractive potential to the cations with a consequent reduction of the F-band energy from the point-ion value [2]. In compounds with relatively large anions, the added attractive potential at the anions is much reduced and no longer significantly depresses the F-band energy. In order to improve the agreement with experiment like Bartram et al. [1], we have diminished all of the $A_\gamma$'s by an adjustable parameter $\alpha$. For each values of $\alpha$, the parameters $\xi$ and $\xi'$ were optimized for 15 alkali halides. Then if we considered the relation $R = (r_-/r_+)$, the expressions (35) and (36) that we obtained for all alkali halides in Table IV are just for small $R$. It means, that relation between the absorption energy of F-center ($E_F$) and parameter $\alpha$ is so good for larger cations and the parameter $A_\gamma$ is reduce more than 57%, except for NaF. It can be seen from Table IV, that the $\alpha$'s increase if the interionic distance $a$ increase too.
It is important to mention that the values of absorption energies from function type I cannot be optimized and we do not include the results in this paper. Function of type III gives a better approximation to the ground state than to the excited states and function of type II is better for excited states, however function of type III is better to calculate the absorption energy of F-center. Function of type I describes qualitatively a Coulomb potential that is similar to the potential of the negative ion vacancy of F-center, but it does not consider the oscillations of potential like functions of type II and type III.

Other trial wave functions have been used. Ong and Vail [10] used a Gaussian localized spherically symmetry wave function and considered the lattice distortion. Dochy [13] included in his work a wave function that is an exact solution for a cuspless hydrogenic potential for the ground state, and for the excited state a type I function with $\alpha = 1$. Renn [14] took Dochy’s functions and the theory developed by Stumpf [15], Brown and Vail [16,17] considered a saddle-point configuration of the F-center using a gaussian-localized wave function. Vail and Harker [18] considered flexible, symmetry-adapted trial pseudowave functions. In recent years there have been major developments in the field, namely, the computer analysis of the electronic state from first principles, the applica-

tion of the method of lattice statics and new methods for taking into account the ionic polarization [19,20,21].
